1. **PROJECT PURPOSE AND NEED**

Stevens Creek Quarry (SCQ) is a 147-acre mining and processing operation located in southwestern Santa Clara County (County) in the Monte Bello Ridge Canyon (as shown in Figure 1, “Regional Location,” and Figure 2, “Site Location”). SCQ and its predecessors have continuously mined for aggregates at the quarry for more than 80 years. The quarry consists of two parcels: Parcels A and B. Parcel A contains the offices, scales, and a concrete recycling facility. Parcel B contains the quarry pit, rock crushing, screening, sorting and conveying equipment, overburden stockpiles, haul roads, and ponds. SCQ operates under the Stevens Creek Quarry Reclamation Plan Amendment that the County approved in 2009 (2009 Reclamation Plan). The County is the lead agency for the quarry under the California Surface Mining and Reclamation Act (SMARA) and California Environmental Quality Act (CEQA).

1.1 **Need**

In 1983, SCQ developed an updated mine plan covering an area of approximately 147 acres. To meet the requirements of the reclamation plan, a 1.5:1 (horizontal to vertical) (1.5H:1V) cut slope was developed. The County granted SCQ a use permit for Parcel A (Use Permit) in January 1984 (modified September 10, 1996) and granted SCQ continued use of Parcel A for 20 years from February 18, 1995 (i.e., until February 18, 2015).

In 2009, the reclamation plan was amended to provide for long-term stability of slopes, prevent wind and water erosion by stabilizing the soil surface through proper grading and drainage, and implement a revegetation program to establish self-sustaining vegetation cover. Since 2009, interim phase mining slopes failed, causing the surface disturbance to extend past the property line and become steeper.

In 2014, SCQ filed an application with the County to extend the Use Permit. The County Planning Commission delayed the public hearing for the Use Permit renewal to an undetermined date.

On September 27, 2017, the County issued a notice of violation (NOV). Between September 2017 and May 2018 the County and SCQ worked together to resolve the violations identified in the September 2017 NOV. On May 16, 2018, the parties signed a compliance agreement and stipulated order that outlined the violations and proposed resolution. On January 4, 2019, SCQ submitted a corrective action plan that outlined a submittal schedule to address the corrective actions outlined below:

- **Violation 1:** The Upper Pond is located within Rattlesnake Creek.
  
  **Corrective Action:** SCQ is coordinating with the San Francisco Bay Regional Water Quality Control Board (RWQCB) regarding an appropriate solution. The RWQCB’s most recent site inspection occurred on December 7, 2018, with no violations noted. The current approach is to reroute the drainage away from the Upper Pond and Rattlesnake Creek. In consultation with the RWQCB, a new settling basin outside of the high-water mark of Rattlesnake Creek will be established.

- **Violation 2:** The Upper Pond and dam are outside the approved reclamation plan boundary.
  
  **Corrective Action:** The reclamation plan amendment for Parcels A and B will ensure that the Upper Pond and dam are within the proposed reclamation plan boundary.

- **Violations 3 and 4:** The mining-related ground movements are outside the approved reclamation plan boundary.
Corrective Action: The reclamation plan amendment for Parcels A and B will ensure that the mining-related ground movements and associated disturbances are within the proposed reclamation plan boundary.

- Violations 5, 6, and 7: There are failed finished cut slopes.

Corrective Action: The reclamation plan amendment for Parcels A and B will incorporate the recommendations provided in 2019 geologic investigation report.

The County required a conditional use permit and reclamation plan amendment to be submitted by May 31, 2019. In a meeting on April 29, 2019, Mr. Robert Eastwood requested a preapplication submittal, providing the County with the main elements of the application and allowing the County to ensure its concerns will be adequately addressed. This project description is provided based on the County’s request and meets the requirements provided in Section 4.0, page 4, of the corrective action plan.

A revised mine plan has been prepared to provide for aggregate production at SCQ with long-term stability of the slopes. This mine plan has the following slope parameters: 1.5H:1V slopes down to 1,060 feet mean sea level (msl), a 1:1 cut slope from 1,060 feet msl to the bottom of the pit at 700 feet msl, and then backfill of the pit at 3H:1V to 1,060 feet msl. To achieve these slope parameters on the west slope, portions of the west pit boundary are adjusted farther west to provide area to cut the slopes into native stable material and mine out the unstable material within the steeper slopes. This mine plan provides annual crusher feed of 2 million tons (1.33 million cubic yards) per year for 5 years of production at SCQ, approximately 9.5 million cubic yards of reserves with approximately 30 percent waste. The ultimate pit in this mine design will have a maximum depth of 700 feet msl. Overburden generated from mining will be hauled to designated areas and stored temporarily. Ultimately the waste material will be used to backfill the pit and create the 3H:1V fill slopes. After the ultimate pit bottom is reached and mining is complete, the pit can be backfilled up to 900 feet msl. At a minimum, all pit slopes below 1,060 feet msl will be filled to create a 3H:1V slope.

SCQ’s primary goal in operating the quarry is to recover the site’s mineral resources, consisting of high-quality construction sand and gravel, and to support existing and future construction projects in the region. Sand, gravel, and crushed stone are referred to as “aggregates.” These basic raw materials are the first step in the construction process and are used in a large variety of products. Buildings, homes, hospitals, roads, airports, shopping centers, sewer and stormwater systems depend on aggregates. Between 40 and 60 percent of all aggregates are used in public works projects. Sand, gravel, and stone comprise nearly 90 percent of the materials needed to build federal, state, and local roads.

1.2 Objectives

The proposed project is intended to achieve the following objectives:

- amend the existing reclamation plan to include an updated mine and reclamation plan that addresses identified slopes stability issues at the site;
- amend the existing reclamation plan to include a newly located settling basin;
- import of between 6 and 7 million cubic yards of fill for reclamation over the remaining 30-year life of the quarry;
- extend and amend the use permit that currently applies to Parcel A to apply to the entire site (Parcels A and B) for a term of 30 years;
• provide for the continued use of the site for the crushing, processing, and distribution of rock, gravel, sand, aggregate, and soil materials;
• import up to 1 million tons and up to 400 truck trips per year of aggregate for processing and sale using an internal/private haul road from the adjacent Permanente Quarry site, to avoid traffic impacts;
• retain the existing aggregate processing plant, provide for the continued aggregate processing of up to 2 million tons per year;
• if required to meet market demands, provide for maximum annual permitted sales of up to 2 million tons of aggregate material to provide a reliable supply of aggregate materials to meet the existing and future regional market demands; and
• mine in a previously disturbed location already serving as an operating quarry.

1.3 **Purpose**

This application is prepared to amend SCQ’S use permit issued for Parcel A and extend its coverage to Parcel B. Figure 3, “Existing Conditions,” shows the locations of Parcels A and B. The use permit is proposed to include a revised mine plan and import of materials for processing and sale.

An existing roadway located on the adjacent Permanente Quarry property was previously limited to general-purpose and utility company (currently Pacific Gas and Electric Company [PG&E]) access. SCQ began accepting aggregate material in May of 2018 for processing from Permanente Quarry, located north of the facility. The material is a native greenstone mined at Permanente Quarry to expose the limestone layer underneath for excavation and processing. SCQ does not accept limestone that is mined at Permanente Quarry, which is known to contain selenium. The greenstone that will be stored and processed will be staged in Parcel B, northwest of the primary crusher. Based on direction from the County, SCQ ceased importing aggregate from Permanente Quarry in December 2018. Additional improvement and use of this route will depend on approvals by the County and City of Cupertino to accept such materials. The existing roadway that would be used to transport the materials is located on private properties and is not intended for public use. Long-term safety is integrated into the engineered design for stability. A geotechnical analysis has been completed to ensure stability of the final cut and fill slopes. The slope stability results present the minimum factors of safety for each analysis, and these results were provided to the County by Lehigh Southwest Cement Company (Lehigh) as part of a separate land use entitlement process.

This application request also includes amending the 2009 Reclamation Plan to provide for a revised slope design to correct the slope instability identified in the western pit slope, updated plans for stormwater flow, and a new settling basin. The 2009 Reclamation Plan for the quarry includes a combination of backfilling the quarry using on-site materials and importing fill materials that meet applicable clean fill requirements. SCQ proposes to continue to use a combination of on-site material and surplus soil available from regional construction projects. Based on the revised design and an estimate of potentially available on-site fill material, SCQ anticipates that 6 to 7 million cubic yards of fill material would be imported over the remaining 30 years of operation.

This reclamation plan for the quarry has been prepared in accordance with the requirements of SMARA, found in California Public Resources Code (PRC) Section 2710 et seq., Title 14 of California Code of Regulations (CCR) Section 3500 et seq., and the County’s (the lead agency) implementing ordinance (Santa Clara County Surface Mining Ordinance Sections 2.10.040 and 4.10.370).
2. SITE DESCRIPTION

SCQ is a 147-acre mining and processing operation located in southwestern Santa Clara County in the Monte Bello Ridge Canyon (as shown in Figures 1 and 2). Monte Bello Ridge, which defines the southern flank of Rattlesnake Canyon, rises to elevations over 2,200 feet msl. Parcel B is carved into an unnamed hillside that rises to approximately 1,800 feet msl and defines the northern flank of Rattlesnake Canyon. Elevations on the existing quarry site range from approximately 550 feet msl near the main site entrance at the southeast corner of Parcel A to approximately 1,295 feet msl at the northwest corner of Parcel B.

The quarry site occupies an area of approximately 167 acres. As shown on Figure 4, “Parcel Map,” Parcel A consists of two irregularly shaped parcels of 14.15 acres and 66.27 acres, respectively (assessor’s parcel numbers [APNs] 351-18-047 and 351-18-048, respectively). Parcel B consists of two rectangular parcels and narrow wedge-shaped parcel (APNs 351-10-019 [40 acres], 351-10-044 [41.95 acres], and 351-10-040 [4.4 acres] respectively). This reclamation plan amendment also includes 75.55-acres located on portions of adjacent parcels (APNs 351-10-017, 351-10-33, 351-10-039, and 351-11-001) currently owned by Lehigh. SCQ will enter into a license agreement with Lehigh to use the 75.55-acre portion of these parcels to lay back the slope of the mine to establish the requisite factor of safety. These areas are described in detail in Section 3.1, below.

As shown of Figure 3, the southern and western portions of Parcel A consist of forested hillsides developed with one private residence occupied by quarry personnel. Although the residences can be accessed from Parcel A, primary access is via a driveway extending from Montebello Road.

The eastern half of Parcel A has a level pad area occupied by stockpiles of soil and finished product, a truck loading area, an area for recycling of concrete and clean fill, the quarry offices, a machine shop, and parking. Truck scales are located adjacent to the quarry offices, near the site exit. Active mining still occurs on the eastern half of Parcel A. A second machine shop and large outdoor equipment and truck storage area are in the center of the parcel, along with a second truck scale nearby. The Middle and Lower Ponds are in the northwest corner of Parcel A. Based on RWQCB requirements, the use of these ponds will be phased out and replaced with an off-channel basin. An undisturbed hillside vegetated with trees and scrub occupies the northern edge of the parcel, to the north of the Lower Pond.

The majority of Parcel B has been disturbed by mining activities, as shown on Figure 3. Excavated slopes extend along the western, northern, and eastern sides of the parcel, defining the current pit. These cut slopes are approximately 300 feet tall on the west and under 100 feet tall on the east side.

The aggregate processing plant is located in the center of the parcel (see Figure 3), with additional conveyors and screens located about 200 feet south of the main plant. An unpaved access road originating near this equipment climbs the east side of the quarry walls, and then continues northward along the eastern parcel boundary, terminating near the northeast corner of the parcel. The road formerly wrapped around the northern half of Parcel B, ending at a temporary stockpile located on the western parcel boundary, but is now accessible only on foot. Additional stockpiles of soil and processed aggregate are located at various locations in the central pit area.

As noted in Section 3.8, below, stormwater that would be affected by mining activities that would have drained to the Upper Basin will be diverted to a new setting basin located outside of the limits of Rattlesnake Creek. Largely undisturbed tree- and scrub-covered slopes are located along and/or just outside the Parcel B boundaries on all four sides.
3. PROPOSED MINING AND RECLAMATION OPERATIONS

3.1 Mining and Reclamation Overview

Operations at SCQ currently consist of excavation/extraction of aggregate resources (i.e., rock and gravel), processing (crushing and screening) of aggregate resources, materials recycling, material loading and weighing, and material hauling. The property encompasses two parcels: approximately 81 acres on Parcel A, and 86 acres on Parcel B. The quarry’s approximately 147 acres includes the Rich Voss Trucking Company.

The quarry includes an aggregate plant, topsoil plant, and recycle plant for broken asphalt and concrete. Equipment used to harvest rock includes frontend loaders, haul trucks, bulldozers, and graders. Figure 3, provides the current (2018) locations of key quarry features. Figure 5, “Mine Plan,” and Figure 6, “Mine Plan Cross Sections,” show the plans for mining the site.

The site will be reclaimed to an open space condition suitable for future development as allowed under the County Zoning Ordinance at reclamation. After mining is complete, all temporary structures and mining and processing equipment will be removed, finished slopes will be graded and engineered where necessary, fill will be imported and used to backfill slopes to reclamation specifications, and revegetation of the entire quarry site will be performed. The recycling operation may continue after the quarry operation ceases and the site is fully reclaimed per SMARA; however, whether this occurs will be determined in the future by the site owner, based on considerations of practicality and economics.

The topography of the completed Parcel A will be a level pad area. Parcel B will be a broad valley, oriented north-south. The ponds will remain. The quarry floor is planned to have a maximum depth of 700 feet msl, with gently sloping floors that drain southerly and westerly. The operation will not excavate to depths below the local groundwater table.

Cut slopes are planned to be 1.5H:1V slopes down to 1,060-foot msl and 1H:1V cut slopes from 1,060 feet msl to the bottom of the pit (700 feet msl). The bottom of the pit will then be backfilled to 1,060-feet msl to grades not to exceed 3H:1V overall. To achieve these angles on the west slope, portions of the west pit boundary must be adjusted farther west to provide area to cut the slopes into native stable material and remove the current, unstable material within the steeper slopes. Figure 7, “Reclamation Plan,” and Figure 8, “Reclamation Plan Cross Sections,” show the reclaimed topography.

The site is estimated to contain approximately 9.5 million cubic yards of reserves with approximately 30 percent waste. This mine plan provides for 2.6 million tons of material moved annually with the 30 percent overburden waste factor, for a maximum annual crusher feed of 2 million tons (1.33 million cubic yards) per year for 5 years of production at SCQ. Overburden generated from mining will be hauled to designated areas and stored temporarily. The waste material will be used to backfill the pit and create the 3H:1V fill slopes from the pit bottom to 1,060 feet msl. Waste may also be used to backfill the pit up to 900 feet msl.

Table 1, “Mine and Reclamation Plan Data,” provides a summary of key data related to operations and reclamation of the site.

### 3.2 Equipment

Equipment associated with mining, processing, and reclamation activities is listed in Table 3, “Typical Equipment.” The types of mobile equipment and/or machines to be employed are typical excavation equipment, such as a dozer, excavator, self-loading scraper, front-end wheel loader, portable water pump, motor grader, conveyers, and haul trucks. A water truck is used for maintenance of surfaces and dust control. The type of vehicles used varies somewhat over time depending on availability and the introduction of new models to suit different conditions.

A mobile fuel and lubrication truck is used to service vehicles on-site. The fuel/lube truck can carry a limited amount of petroleum products, is equipped with automatic shut-off valves to prevent spills, and also carries appropriate absorbent materials to contain and recover spillage. An approved spill prevention, control, and countermeasures (SPCC) plan guides reporting, control, and cleanup activities in the event of a spill in the quarry or other operating areas.

**Notes:**
1. Equipment will be purchased at the time it is needed and may differ from equipment listed.
2. The equipment listed uses diesel fuel.
3.3 Overburden Management

Approximately 30 percent of the materials mined are expected to be overburden. Overburden generated from the mining will be hauled to designated areas and stored temporarily. Overburden will remain on-site to be used for reclamation (i.e., for backfilling the pit and creating the 3H:1V fill slopes from the pit bottom up to 1,060 feet msl).

The temporary overburden stockpiles will be managed for erosion as prescribed by the current storm water pollution prevention plan (SWPPP). Best management practices (BMPs) related to stockpiles include 2H:1V slopes to reduce erosion, placement of obstacles (e.g., straw wattles) at the base of stockpiles to contain sediment, and watering and/or hydoseeding surfaces to prevent dust.

3.4 Aggregate Processing

Haul trucks transport the raw materials from the excavation to the primary crusher at the aggregate plant. The raw material is processed through primary and secondary crushing and screening to meet specifications for sand, gravel, and crushed-stone products. The fines are further processed using a dewatering screen along with coarse and fine sand screws. The ultra-fine material is then processed through a plate press. The material is then conveyed to individual stockpiles for shipment.

3.5 Imported Materials

3.5.1 Recycling Materials

The recycling operation, including storage of materials, is maintained in a manner that keeps adjacent streams, lakes, and percolation ponds free of siltation, contamination, or pollution. Retention devices will be installed and maintained to control sediments so that they are not deposited in Stevens Creek Reservoir. The recycling operations are currently located in the area shown Figure 3.

3.5.2 Raw Aggregate

As noted in Section 1.2, SCQ began importing material via 45-ton articulated haul trucks on the previously improved road between Permanente Quarry and SCQ. The aggregate material is loaded at Permanente Quarry into SCQ’s truck using a wheeled loader. Up to 400 roundtrip truck trips will occur daily along this road. Use of this private road will keep these haul trucks off public roads. The hours for these truck trips will be the same as for the operating hours specified in Table 1, above.

3.5.3 Fill Materials

Fill will be imported to the site to achieve final reclamation. The following subsections describe the planned import and placement process.

Fill Import

Depending on conditions at the particular construction site, excess fill generated at a construction site can contain hazardous substances or other characteristics that require disposal at facilities permitted to receive such materials (i.e., landfills). However, much of the fill generated at construction sites does not require disposal in a landfill and may be suitable for reuse as fill material for development projects, public works projects, and land improvement projects, including reclamation. SCQ is located in the southwestern portion of the San Francisco Bay Area, where fill is typically moved by truck from construction sites to reuse/disposal sites. Transportation cost and efficiency are important factors in fill reuse/disposal decisions. Construction and hauling companies typically seek to
minimize transportation costs and optimize efficiencies by selecting reuse/disposal locations that minimize cost, travel time, and travel distance. It is anticipated that sufficient supplies of fill for SCQ reclamation will be available from construction activities within the San Francisco Bay Area.

Fill materials imported and used for reclamation purposes are limited to earth. No construction or demolition waste regulated under CCR Title 14, Section 17388.3 is to be used for fill for reclamation. Fill is compacted, tested, and documented to demonstrate it supports postmining uses.

**Fill Placement**

Compaction is not required for the end use, but is typically employed in practice by the loading imposed by the heavy hauling equipment and heavy, tracked vehicles. Backfill will become compacted after two to five passes with a truck or dozer. Backfill is currently placed concurrently with mining. The fill placement is depicted in the mine plan and mine plan cross sections (Figures 5 and 6).

Backfill will occur from the bottom upward. Material will be placed in lifts according to the predominant material type within the lift (either greenstone overburden or imported fill). Adequate compaction will be achieved by truck and dozer traffic, as the lifts are advanced. The final backfilled surface will slope at 2 percent toward the east end of the south wall, which is the lowest area of the surrounding topography.

### 3.6 Transportation

The following subsections provide details related to on- and off-site transportation for mine operations and site reclamation.

#### 3.6.1 Public Road Access and Routes of Travel

Three driveways (as shown in Figure 3) currently provide vehicular access to Parcel A from Stevens Canyon Road:

- the main entrance near the southeast corner of Parcel A, used for ingress only;
- an exit-only driveway located about 180 feet northeast of the entrance; and
- a third driveway at roughly the midpoint of the site’s frontage on Stevens Canyon Road, used infrequently by trucks that have already been weighed.

Opportunity and efficiency exist to reduce vehicle emissions and local roadway traffic and increase efficiency by providing for client access from the adjacent Permanente Quarry. Reclamation planning for the portion of the haul road that connects the SCQ property to the Permanente Quarry property is incorporated into the amended reclamation plan.

A gated (locked) entrance at the northeast corner of Parcel A is used by the City of Cupertino for access to compost facilities that are part of a City program.

#### 3.6.2 Vehicle Trips and Haul Routes

Activities at SCQ are restricted by the number of truck trips that are permitted to exit the quarry each operational day. The conditions establish a limit of 1,300 (roundtrip) on-road trips of material loads per day, excluding trucks using the private road to Lehigh’s site, the use of which will keep additional haul trucks off public roads. A load is the total material hauled on-road by single motorized vehicle, i.e., the
amount a single driver can haul. This condition is not expected to change under the proposed project. Stevens Canyon Road, Foothill Boulevard, Highway 280, and the Foothill Expressway are to be used as haul routes.

3.7 Water Supply and Use

Quarry operations require water for dust control and aggregate processing. This water is supplied from stormwater stored in ponds and settling basins.

3.8 Surface Water Management

In general, the site is bisected by Rattlesnake Creek and is surrounded by mountainous terrain that is heavily vegetated with varying slopes. Swiss Creek meanders around the southern edge of the quarry and receives flow from Rattlesnake Creek, No Name Tributary, and Montebello Road. Swiss Creek then flows through a culvert that passes under Stevens Canyon Road and discharges into Stevens Creek Reservoir. The elevation of the facility ranges from approximately 1,270 feet msl at the top ridge in Parcel B to approximately 550 feet msl near Outfall No. 4 (OF-4). Appendix A, “SWPPP Site Maps,” shows the location of OF-4 (specifically, Figure 3a of the SWPPP). Surface drainage at the facility generally flows southeast toward Stevens Creek Reservoir. Stormwater is conveyed through culverts, French drains, concrete swales, and drainage ditches to sediment traps, sediment ponds, and an on-site stormwater storage tank.

The stormwater drainage area contributing to run-on from off-site areas is estimated to be approximately 39.3 acres (13.6 acres from Drainage Area 5 and 25.7 acres from Drainage Area 2). (See Appendix A for a depiction of the drainage areas). The National Pollutant Discharge Elimination System (NPDES) General Permit for Storm Water Discharges Associated with Industrial Activities (Industrial General Permit) requires BMPs to be implemented to direct off-site and nonindustrial run-on away from industrial areas and erodible surfaces. Berms, drainage ditches, drop inlets, sediment traps, silt fences, check dams, and straw wattles will be implemented to meet this requirement. These BMPs will be located along the quarry roads and throughout the facility as necessary. The off-site drainage areas and associated stormwater conveyance facilities or BMPs are shown on Figures 3a and 3b in Appendix A.

Bay Area Geotechnical Group (BAGG Engineering) designed and engineered a new settling basin. The new settling basin will be located northeast of Sediment Pond 4. See Appendix B, “BAGG Technical Report” (Plate 3, “Site Plan Proposed Topography”), for the location and design of the new settling basin. The two water tanks at the current location will be relocated. The new settling basin will be designed to comply with design storm standards in the Industrial General Permit. For volume-based BMPs, the design storm standard is the ability to meet an 85 percentile 24-hour storm event as determined from local, historical rainfall records.

An overflow structure will be constructed as part of new settling basin development to prevent the water level in the pond from overtopping the development access road, which will function as a dam once raised by 10 feet. The increased height of the development access road will allow for a desirable pond capacity. The capacity of the dam will not reach or exceed the California Division of Safety of Dams’ (DSOD’s) 15-acre-foot jurisdictional threshold capacity. The new settling basin capacity is estimated to be approximately 4.4 acre-feet provided that the pond’s side slopes are cut at an approximate gradient of 2H:1V and the development access road is raised by 10 feet at an approximate 1.5H:1V gradient.
As part of the terms of a discharge permit from the RWQCB, the SCQ operator regularly monitors water quality of the discharge from the quarry and is required to submit quarterly monitoring reports to the RWQCB.

3.9 Hazardous Materials

Existing water quality protection measures at the facility are described in the SWPPP (last updated November 30, 2018), the SPCC plan (last updated September 19, 2014), and the hazardous materials business plan (last updated June 2016). The SWPPP describes stormwater drainage facilities, identifies possible water pollution sources that could affect the quality of stormwater discharged from the facility, and, as described in Section 3.8, documents BMPs that have been implemented to minimize or prevent discharge of pollutants that may be in stormwater.

Materials present at the facility that may contribute pollutants to stormwater runoff that are identified in the SWPPP include rock, gravel, sand, silt, clay, petroleum products (fuel, oil, grease), antifreeze, batteries, waste oil, and new and/or spent solvents. Detailed information regarding potential pollutants associated with each potential source area and the BMPs implemented for each area are identified in Table 6-1 of the SWPPP. The SWPPP will be updated to reflect the new settling basin and additional BMPs that are being implemented at the site in response to comments received from the RWQCB.

Any waterbody created during operations will be maintained in such a manner as to provide mosquito control and to prevent the creation of health hazards or public nuisance.

3.10 Security and Fencing

Fencing of the property will be installed and maintained in good condition as described in the following list:

a) A 5-foot-high chain-link fence will be maintained along the right-of-way of Stevens Canyon Road.
b) A four-strand barbed-wire fence will be maintained along the property line with Sunnyvale Rod & Gun Club.
c) The fence opening between Sunnyvale Rod & Gun Club will be closed.

3.11 Reclamation

SMARA requires mines to be reclaimed to a usable condition that is readily adaptable for a productive alternative land use that does not endanger public health or safety. Proposed reclamation is shown on Figure 6 and Figure 7. The plan provides for an open space condition for the site that is suitable for postmining use under the County’s general plan and zoning code designation for the site and consistent with historical use of the property. Following the completion of mining and reclamation activities, equipment associated with mining and processing would be removed from the site, including, but not limited to the office building, scale, screens, and conveyors. Species to be planted will consist of shrubs and trees that have evidenced good success on disturbed soils, and are prompt generating grasses that are acclimated to local conditions. The removal, handling, and replacement of soil to be used in reclamation would be accomplished in accordance with State Mine and Geology Board reclamation performance standards.
3.11.1 Slope Stability

Section 3.1 provides an overview of the cut and fill slopes. Figures 4–7 provide the slope design. Slopes angles are revised to provide for aggregate production at SCQ and long-term stability. This mine plan has the following slope parameters: 1.5H:1V slopes down to 1,060 feet mean sea level (msl), a 1:1 cut slope from 1,060 feet msl to the bottom of the pit at 700 feet msl, and then backfill of the pit at 3H:1V to 1,060 feet msl. To achieve these slope parameters on the west slope, portions of the west pit boundary are adjusted farther west to provide area to cut the slopes into native stable material and mine out the unstable material within the steeper slopes. One 100-foot bench is included within the western slope at 1,060 feet msl to provide additional long-term stability.

3.11.2 Fill Placement

As described in Section 3.1, after completion of mining, the bottom of the pit will be backfilled to 1,060 feet msl to grades not to exceed 3H:1V overall. To achieve these angles on the west slope, portions of the west pit boundary must be adjusted farther west to provide for area to make the cut slopes into native stable material and remove the current, unstable material within the steeper slopes. Figure 7 and Figure 8, show the reclaimed topography. Suitable on-site fill will be used to backfill the pit. To the extent additional fill will be required, Section 3.5.3 provides additional detail regarding the importation and placement of fill material.

April 17, 2019
BAGG Job No: STEVE-18-03

Mr. Jason Voss
jvoss@scqinc.com
Stevens Creek Quarry, Inc. (SCQ)
California Mine ID 91-43-007
12100 Stevens Canyon Road
Cupertino, California 95014

Dear Mr. Voss:

Bay Area Geotechnical Group (BAGG Engineers) is pleased to present the results of our engineering geologic and geotechnical evaluation performed for the proposed New Settling Pond (NSP) planned within the active Stevens Creek Quarry (SCQ) in Cupertino, Santa Clara County, California. The attached Plate 1, Vicinity Map, delineates the general location of the proposed New Settling Pond within the quarry while Plate 2, Site Plan Existing Topography, shows the area of the pond where we advanced our borings and extended three structural cross section lines. Plate 3, Site Plan Proposed Topography, depicts the proposed cut slopes and New Settling Pond outline in addition to delineating the location of our borings, cross section lines, Upper, Middle and Lower Settling Basins, adjacent Property line, surface disturbance boundary marking the limit of the planned cut, the Pacific Gas and Electric Company (PG&E) adjacent easement, and the Development Access Road (DAR).

This engineering geologic/geotechnical investigation and slope stability analysis was performed in general accordance with the scope of work described in our proposal No. 18-406, dated October 25, 2018.

SITE LOCATION AND PROJECT DESCRIPTION

The proposed NSP is planned along the east side of the DAR generally opposite the existing Lower Settling Basin (LSB) within the active SCQ at a location that is nearly 2,300 feet to the southeast of the active mining pit at the quarry. The area of the NSP is currently occupied by a topographic knob that extends about 120 feet in height above the adjacent DAR. The topographic knob is comprised of a southwest-
facing slope that will be cut to accommodate the NSP and the cut will be extended upslope to near the property line. Nearly immediately beyond the property line, the southwest-facing slope breaks and descends facing to the northeast. The western side of the noted existing topographic knob abutting the DAR along its northeastern side has been cut previously to a relatively steep slope (1H:1V [Horizontal to Vertical] or steeper) exposing sandy/gravelly sediments belonging to the late Pliocene/early Pleistocene terrestrial sedimentary Santa Clara Formation, to permit the extension and construction of the DAR and access to the mining pit. A 100-foot wide PG&E overhead high voltage transmission easement is present just beyond the quarry’s property line to the north. Two steel lattice towers supporting the high voltage power lines are present to the northwest and northeast of the site area just beyond the property line. An overflow structure will be constructed as part of NSP development to prevent the water level in the pond from overtopping the DAR, which will function as a dam once raised by 10 feet opposite the NSP.

The topographic knob will be cut starting at near the prominent bend in the property line and carried downslope towards the southwest to create south- and southwest-facing slopes to permit the construction of the NSP as depicted on Plate 3. The NSP slope cuts were initially proposed at an approximate gradient of 1.5H:1V. However, our stability analyses results indicated that the noted 1.5H:1V NSP cut slope gradient was not considered stable under seismic loading. We understand that the portion of the DAR to abut the planned NSP along its western side will be raised about 10 feet in height to help achieve a desirable pond capacity, which will not reach or exceed the 15-acre-foot jurisdictional threshold capacity. It is important to note that the level area traversed by the DAR used to be occupied by a tributary creek channel to the main Stevens Creek channel, which has been infilled and dammed in few places to create the Upper, Middle and Lower Settling Basins and extend the DAR shown on Plates 2 and 3.

PURPOSE AND SCOPE OF SERVICES

The purpose of our services was to investigate and characterize the subsurface conditions at the location of the NSP and evaluate the stability of the proposed cut slopes. Furthermore, once we established a stable cut slope configuration under static and seismic loading, we estimated the Acre-foot capacity with the DAR raised by 10 feet as noted above. Specifically, our scope of work included the following elements:

- Review pertinent published geologic and seismic reports and maps prepared by the California Geological Survey (CGS) and the U.S. Geological Survey (USGS) in addition to site-specific geotechnical/geologic reports and studies prepared by consultants such as Norfleet Consultants (Norfleet) in 2008 and BAGG Engineers in 2019;
- Perform slope reconnaissance of the site area by our Certified Engineering Geologist (CEG);
- Explore and investigate the subsurface conditions by advancing six (6) borings to depths ranging between 29 and 84 feet. Borings B-1 through B-3 drilled along the DAR varied in depth between 29 and 30.5 feet below ground surface (bgs) while Borings B-4 through B-6 drilled atop the topographic knob ranged between about 74.5 and 84 feet in depth bgs;
- Perform geotechnical laboratory testing on some selected samples;
- Generate three geologic structural cross sections: A-A’ through C-C’;
- Evaluate the collected data and perform slope stability analyses under static and pseudo-static (seismic) loading conditions depicting several slope gradient scenarios;
- Meeting attendance and consultation with the quarry manager;
- Calculate the NSP capacity once a stable cut slope configuration was established; and
- Prepare this letter report summarizing our findings, conclusions, and recommendations to attain satisfactory factors of safety based on our analysis of the three geologic cross sections (A-A’ through C-C’) that were extended in a roughly perpendicular fashion to the planned cut slope along the east and north sides of the proposed NSP. This report includes a vicinity map, two site plans, an area geologic map, laboratory testing results, geologic cross sections, and stability analysis plots.

PROJECT BACKGROUND

Initially, the cut slopes along the east and north sides of the proposed NSP were to be cut at a slope gradient of 1.5H:1V. However, our stability analysis indicated that such gradients were not considered stable under seismic loading although acceptable Factors of Safety (FOS) exceeding 1.5 were obtained under static conditions. No intermediate drainage terraces/benches were planned as part of the original design.

Based on the obtained stability analysis results discussed above for the initially-planned 1.5H:1V gradient, we also analyzed 1.75H:1V and 2H:1V slope configurations with a mid-slope height drainage terrace/bench. In addition, we analyzed the cut slope stability under the assumption that they would be over-excavated 20-30 feet (measured perpendicular from the slope face) and then rebuilt as engineered fill reinforced with geogrid and even utilizing aggregate base for the keyway excavation at an approximate 1.5H:1V gradient. Acceptable FOS were only attained utilizing the 2H:1V cut gradient under seismic loading, however. The 2H:1V configuration would result in shifting the toe of the proposed cut slopes to the west and southward, which would alter the layout of the NSP and decrease the pond’s capacity. To address the pond’s capacity reduction, we understand that the DAR will be raised by 10 feet where it abuts the planned NSP.

GEOLOGY AND SEISMICITY

Area and Site Geology

The site area has been mapped by several mappers including Dibblee (1966), Rogers (1972), Rogers and Armstrong (1973), Rogers and Williams (1974), Sorg and McLaughlin (1975), Brabb et al. (1998), Brabb et al. (2000), Norfleet Consultants (2008), Dibblee and Minch (2007), and BAGG Engineers (2019). The topographic knob which will be cut to create a location for the NSP is underlain by lower Quaternary (Pleistocene) and upper Tertiary (Pliocene), non-marine sedimentary bedrock belonging to the Santa Clara
Formation, which is described by Sorg and McClaughlin (1975) as: semi-consolidated, poorly to moderately lithified, pebble to boulder conglomerate, fine- to coarse-grained poorly sorted sandstone, siltstone, and clayey mudstone of fluvial and lacustrine origin. Upper half of formation predominantly conglomerate and interbedded medium- to coarse-grained sandstone. Lower half of formation composed of about equal percentages of pebble conglomerate and interbedded medium- to fine-grained sandstone, siltstone, and clayey mudstone and locally contains peat-rich layers with well-preserved plant remains and carbonized wood fragments up to 6 feet long.

Brabb et al. (1998) noted that the formation consists of irregular and lenticular beds and that its thickness is variable but reaches a maximum of about 500 meters (about 1,650 feet). The Santa Clara Formation in this area is separated from the Cretaceous and Jurassic age Franciscan Complex greenstone bedrock to the west by the Berrocal fault, which is a high-angle reverse fault dipping between 50 to 70 degrees to the west. The Franciscan Complex greenstone bedrock to the west of the fault appears to have been thrust over the terrestrial and younger Santa Clara Formation sedimentary units along the faulted contact rendering the older marine Franciscan units atop the younger Santa Clara Formation sediments. Beyond the fault zone and the NSP site area to the northwest, the SCQ main active mining pit and surrounding slopes expose Franciscan greenstone bedrock exclusively that is closely and highly fractured, sheared, and foliated. Norfleet (2008) indicated that it is unlikely that a specific fault plane is present along the contact separating the two rock types and that the fault is represented by a shear zone measuring between 50 to 100 feet in width and which extends along the east side of the quarry’s main mining pit. The fault zone extends northeastward between the NSP site and the quarry’s active mining pit before making a prominent bend to the northwest. The upper approximately 40 to 60 feet of the greenstone bedrock appeared weathered and colored yellowish brown due to oxidation while the greenstone bedrock exposed on the lower mined slopes generally appeared greenish gray due to reduction below the upper oxidized zone.

Sorg and McClaughlin (1975), Brabb et al. (1998), Norfleet (2008) and BAGG Engineers (2019) mapped a prominent fault-related shear zone that bifurcates off the main fault trace immediately to the northwest of the NSP site and extends in a northwest trend extending diagonally across Parcel B of the quarry where the active mining pit is located. Our CEG observed the diagonal shear zone along the north end of the Western Rim Slope (near the northwestern corner of the quarry mining pit) where it consisted of several steep shear planes some of which were lined with plastic greenish clayey gouge. The noted shears extended the entire height of the approximately 400-foot high mined slope and several of the shear planes appeared to strike east/west and dip steeply to the south with one prominent shear plane trending northwestward and dipping steeply to the southwest. Norfleet (2008) shows the shear zone as a band of serpentine that extended through the greenstone bedrock and although our CEG observed the shear zone on the initial cut near the northwestern corner of the active mining pit, our CEG did not observe the serpentine rock band delineated by Norfleet in 2008 as the area was underlain by greenstone entirely. As noted above, the main trace of the Berrocal fault is shown by most of the mappers to extend along the east side of the active mining pit after making a prominent northeast bend immediately to the northwest.
of the subject site. The portion of Brabb et al. (1998) geologic map that covers the site area is included as Plate 4, Area Geologic Map.

**Landslides**

None of the referenced mappers delineated landslide deposits in the area of the topographic knob where the NSP is planned. However, most mappers show large-scale landslide deposits, which have occurred in Franciscan Complex greenstone and sheared Franciscan mélangé rocks across and beyond the infilled creek channel and LSB to the west. However, these mapped landslides do not extend across the DAR and do not appear to impact the NSP site.

The western portion of the topographic knob where the slope has been cut steeply to accommodate the extension of the DAR is shown by the CGS on their regulatory Seismic Hazard Zone maps (2002a) to be within a Seismic Hazard Zone associated with earthquake-induced landslides. Plate 2.1 (Landslide Inventory Map) of the Seismic Hazard Zone Report 068 (SHZR 068) prepared by the CGS (2002b) for the 7.5-Minute Cupertino quadrangle shows the area of the site to have been graded significantly but no landslides are shown at or in the vicinity of the site. In agreement with previous mappers, the CGS (2002b) also shows the same large-scale landslides across the infilled creek channel/DAR and LSB to the west. The site area was not shown to be within a Seismic Hazard Zone associated with soil liquefaction, however.

**Faulting and Seismicity**

The main trace of the Berrocal fault has been mapped by Sorg and McLaughlin (1975), Brabb et al. (1998), and Dibblee and Minch (2007) to extend roughly in a northwest trend along the west side of the now infilled creek channel and the LSB and it does not encroach onto the site limits. The referenced mappers show the main fault trace to extend beneath the landslide deposits mapped to the west of the former and now infilled creek channel and the LSB.

The Berrocal fault has not been zoned as active by the Division of Mines and Geology (DMG, 1974 and 2000) because it does not meet their zonation criteria. However, while the fault is within a County of Santa Clara Fault Rupture Hazard Zone (SCC, 2012), the fault trace and the associated hazard zone delineated by the County of Santa Clara do not encroach onto the site of the NSP.

The San Andreas fault is mapped about 2 miles to the southwest and the Monte Vista-Shannon fault is mapped about 1.3 miles to the northeast of the site area. Norfleet (2008) indicated that while the quarry was active during the Loma Prieta Earthquake of October 17, 1989, the quarry personnel reported that the quake did not cause rockfalls or slope failures and only a single water glass fell off a counter in a nearby house. Furthermore, Norfleet (2008) indicated that a study of aftershocks from the 1989 earthquake in the Santa Cruz Mountains performed by Lindley and Archuleta (1994) found that Franciscan ridgtops had little ridgtop amplification and shatter and that the average amplification at Franciscan Complex sites was 3 times less than amplification at sites underlain by Tertiary (Miocene and Pliocene) bedrock.
FIELD EXPLORATION AND LABORATORY TESTING

Subsurface conditions at the site were explored between December 17 and 20, 2018 by drilling six borings designated as Borings B-1 through B-6 to depths varying between about 29 and 84 feet bgs at the approximate locations shown on the attached Plates 2 and 3. The borings were advanced utilizing a truck-mounted drill rig equipped with 8-inch diameter hollow stem augers. An access route was pioneered by the quarry operator immediately to the northwest of the site generally opposite the existing Middle Settling Basin so that the drill rig is able to access the top of the knob. Furthermore, the quarry operator also provided a bulldozer to pull the drill rig up the cut access road and across dips and soft spots. Borings B-1 (29 feet deep) and B-2 (30.5 feet deep) were drilled along the DAR to assess the feasibility of placing fill to raise the DAR in the vicinity of the proposed NSP. Boring B-3 (30.5 feet deep) was advanced in the level area just beyond the topographic knob to the southeast. Borings B-4 (74.5 feet deep), B-5 (79 feet deep) and B-6 (84 feet deep) were drilled atop the topographic knob where equipment access was feasible. The intent of drilling atop the knob to the noted depths was to assess the condition of the formation where the planned cut slope face is projected to be encountered/exposed and to evaluate the bedrock rippability down to near the maximum planned cut planned.

A professional geologist with our firm technically directed the exploration, maintained a continuous log of the borings, and obtained disturbed bulk and Standard Penetration Test samples in addition to relatively undisturbed ring samples utilizing Modified California Sampler for laboratory testing and subsequent visual examination.

The obtained subsurface materials were visually classified in the field and the classifications were then checked against the results of the laboratory testing program. In addition to sample classification, the boring logs contain interpretation of where stratum changes or gradational changes occur between samples and also the obtained laboratory test results. The boring logs depict BAGG’s interpretations of subsurface conditions only at the locations indicated on Plates 2 and 3 and are intended for use by SCQ only in conjunction with this report, and only for the purposes outlined by this report.

Selected undisturbed samples were tested in direct shear to evaluate the strength characteristics of the subsurface materials. Direct shear tests were performed under natural moisture and artificially increased moisture contents, while under various surcharge pressures. Atterberg Limits tests were performed on clayey site samples to help define the plasticity characteristics and aid in the soil classification. Washes over a #200 sieve were also conducted to assist in the classification of fine-grained soil samples and moisture content and dry density measurements were also performed on undisturbed samples to aid in correlating their engineering properties. The results of our laboratory strength tests, Atterberg Limits tests, classification tests, and moisture/density measurements are summarized on the boring logs and/or plates identified below.
SITE CONDITIONS

Surface Conditions
The topographic knob, which will be cut to accommodate the construction of the proposed NSP, exceeds 100 feet in height and, as noted above, its southwestern sloping side abutting the DAR has been cut to an approximate 1H:1V steep gradient exposing sandy/gravelly sediments belonging to the Santa Clara Formation. Farther upslope beyond the noted side cut, the topographic knob’s surface and side slopes are irregular and covered with heavy brush and tree growth.

Subsurface Conditions
The Santa Clara Formation is relatively young geologically and its various comprising interbedded sedimentary units are lenticular in shape and somewhat discontinuous laterally. And although it is considered by geologists to be formational bedrock, it is generally unconsolidated, weakly lithified and poorly cemented. The formation’s composition varies significantly laterally and with depth and its physical characteristics and engineering properties resemble soil-like materials rather than coherent bedrock. Depending on the geographical locality around the San Francisco Bay, the formation’s sand/gravel content varies significantly with the upper sections of the formation containing more sand and gravel while its lower section is comprised mostly of silt and clay.

Borings B-1 through B-3 drilled along the DAR and the base of the topographic knob generally encountered up to about 7.5 feet of old fill that was most likely placed there as part of the DAR extension and construction. Borings B-4 through B-6 were drilled along the top of the knob and they revealed between 2 and 3 feet of residual soils that have developed in-place into lean clays through the chemical decomposition of the minerals comprising the formation. Beneath the fill in Borings B-1 through B-3 and below the residual soil section encountered in Borings B-4 through B-6, the borings generally revealed dense to very dense silty and clayey sand layers with varying mixtures of gravel that are interbedded with hard layers of lean and minor fat clays. Nearly all the borings met practical refusal where 50 blows were recorded for 6 inches or less of sampler penetration.

Our interpretations of the subsurface conditions as extrapolated from the information obtained during our site reconnaissance, subsurface exploration and published geologic literature, are presented on Cross Sections A-A’, B-B’ and C-C’ presented as Plate 5, Geologic Cross Sections. More detail pertaining to the subsurface conditions is presented in the boring logs.

Groundwater
Groundwater was not encountered in any of our borings although perched free water was detected in Boring B-3 between about 8 and 9 feet bgs. Based on input from the quarry operator, groundwater has not been encountered at the quarry area for as long as it has been functional. In addition, the quarry operator reported that a well drilled at a residence within the immediate area of the quarry did not encounter a groundwater phreatic level. Isolated seepages were observed along the mined slope faces surrounding the active quarry pit to the north and free water seems to always be present within the main mining pit and also within the Upper, Middle, and Lower Settling Basins. However, this noted free water
is detained storm water runoff and not groundwater. It is important to note that groundwater levels can vary seasonally due to inclement weather and irrigation activities. As the DAR is raised by approximately 10 feet higher in the immediate area of the NSP, we understand that water detained within the NSP will be about 2-3 feet lower than the road crest after it has been raised.

The graphical representation of the materials encountered in the borings and the results of our laboratory tests, as well as explanatory/illustrative data, are attached to this report as follows:

- Plate 6, Unified Soil Classification System, illustrates the general features of the soil classification system used on the boring logs.
- Plate 6A, Soil Terminology, lists and describes the soil engineering terms used on the boring logs.
- Plate 7, Rock Terminology, lists and describes the engineering terms with respect to bedrock classification used on the boring logs.
- Plate 8, Boring Log Notes, describes general and specific conditions that apply to the boring logs.
- Plates 9 and 9B, Key to Symbols, describes and defines various symbols used on the boring logs.
- Plates 10-A through 15E, Boring Logs, provide detailed descriptions of the subsurface materials encountered, show sample depths and blow counts and summarize the results of the laboratory testing.
- Plates 16 and 17 present plotted laboratory test results for gradation and Atterberg Limits testing performed as part of our study.
- Plate 18 includes direct shear test plots and how we derived the selected strength parameters for the Santa Clara Formation.
- Plots 19 through 24 present results of the slope stability analyses.
The initially-planned grading scheme indicated that 1.5H:1V cuts that originate near the property line and extend downslope generally facing southward along Cross Section A-A' and southwestward along Cross Sections B-B' and C-C' would be made. Our stability Cross Sections (A-A', B-B' and C-C'), which were extended upslope to near the top of slope where the subject slope crests before it breaks and descends facing northeastward, were extended nearly perpendicular to the proposed cut slope contour lines. The base of the proposed pond was set at about 10 feet below the existing DAR elevation. However, our slope stability analyses indicated that the 1.5H:1V and the 1.75H:1V slope gradient cut in Santa Clara Formation sediments would not be stable under seismic loading although satisfactory FOS were obtained for the noted gradients under static conditions. The capacity of the NSP at such gradients was not checked since the 1.5H:1V and 1.75H:1V gradients were not deemed stable under seismic loading.

As part of our analyses, we also assumed that a 30-foot wide band, measured perpendicular from the slope face, is cut and the generated earth materials is then placed back as geogrid-reinforced engineered fill (GF) buttress that is supported on a 30-foot wide and 15-foot deep base keyway. However, our analyses indicated that such a remedial grading scheme would also be unstable under seismic loading. To further assess the feasibility of the original 1.5H:1V slope gradient, we also assumed the lower keyway excavation would be filled with aggregate base (AB) instead of soil and even replaced the entire buttress with AB but the obtained results indicate that the 1.5H:1V configuration would only be stable under seismic loading if the keyway depth and width are increased to 30 feet and 100 feet, respectively.

Based on input from the quarry manager, we analyzed a flatter 2H:1V gradient for the cut slopes along all three cross sections with an 8-foot wide drainage terrace/bench at near mid-slope height. The results of our stability analyses indicated that the 2H:1V slope gradient for the planned cut slopes is stable under both static and seismic loading conditions for all three cross sections. We calculated the planned NSP capacity with the stable 2H:1V configuration to be around 2 acre-feet (AF), if the DAR remains at its current elevation. With additional input from the quarry manager and to increase the NSP capacity, we modeled placing engineered fill and raising the DAR about 10 feet higher than existing and extended the base of the 2H:1V excavation until the toes of the planned cut slopes along all sections converged with the opposing northeast-facing DAR slope noting that the DAR side slope would be deepened at a 1.5H:1V gradient. Under this grading scheme, we estimated the NSP capacity to be about 4.4 AF. A discussion pertaining to the selection of earth material strength parameters utilized in our analyses and the obtained stability analyses results are presented below in the following paragraphs.

**Slope Modeling and Analysis Method**

The stability of the cut slopes was evaluated with the conventional method of limit equilibrium stability analysis on two dimensional slope cross section with the aid of the computer program GeoStudio 2019 (Slope/W). Our analysis used the Morgenstern-Price Method, which considers both interslice shear and normal forces of the individual slices, into which the soil mass above the failure surface is divided, and
includes both moment and force equilibrium. Various trial failure surfaces are analyzed in this manner until a minimum factor of safety is obtained.

**Soil Strength Parameters**

For stability analysis purposes, three (3) earth material types were established, which include Santa Clara Formation (QTsc), geogrid-reinforced fill (GF) and aggregate base (AB). As noted above, remedial grading schemes that included GF and AB were not deemed stable under seismic loading and although we discuss strength parameters we utilized for the GF and AB, we have selected not to include any stability analysis plots in this report where the GF and AB were utilized. We have only included stability analysis results and plots for 2H:1V cut slope gradients where acceptable FOS were achieved.

Strength tests on selected QTsc soil samples consisted of direct shear tests performed at both natural (field) and artificially-increased moisture contents, while under various surcharge pressures. The results of the direct shear tests are reflected on the boring logs and are presented on Plate 18, Direct Shear Test Plots. The strength parameters of the Santa Clara Formation, including the internal frictional angle and the cohesion, were derived from the obtained test results as is indicated on Plate 18. Conservative strength parameters for the GF and AB were selected based on experience and engineering judgement. The strength parameters for the various earth materials mentioned above are presented in the following table:

<table>

**Static Slope Stability Analysis**

Based on the noted strength parameters and the geometry of Cross Sections A-A’ through C-C’, the results of our slope stability analyses yielded static FOS ranging from about 1.66 to 1.74 for global conditions. We note that these analyses were based on slope configurations with 2H:1V gradients for the cut slopes coupled with an 8-foot wide drainage terrace/bench to be installed at near mid-slope height, and 1.5H:1V for the raised DAR northeast-facing eastern side slope.
Seismic Slope Stability Analysis

The seismic stability of the slopes was analyzed using a pseudo-static approach per the general guidelines included in CGS Special Public Publication 117A (2008) and the Southern California Earthquake Center (2002). Earthquake Engineering Research Institute has published a screening analysis procedure for seismic slope stability (Stewart et al., 2003), which takes into account local variations in the seismicity as presented by the earthquake magnitude, as well as the distance from the fault that most significantly contributes to the ground motion hazard at the site. The screening procedure is based on a statistical relationship previously developed by Bray et al. (1998) between seismic slope displacement (u), peak amplitude of shaking in the underlying bedrock (kmax), significant duration of shaking (D5-95), and the ratio of slope resistance to peak demand (ky/kmax), where ky is the yield acceleration, or the horizontal acceleration required to reduce the safety factor to unity. A tolerable seismic slope displacement (u) for residential range from 5 cm to 15 cm. A safety factor of 1 is the minimum required for passing the screening procedure.

Using the slope screening procedure, a pseudo-static coefficient of 0.29g was estimated for the analysis based on respective deformation of 15 cm. The minimum seismic FOS are approximately 1 for all the three cross sections studied.

The results of our static and seismic slope stability analysis are summarized in the table below. Individual plots of slope stability analyses for various scenarios are presented on the attached Plates 19 through 24.

*Utilizing 2H:1V slope gradients

It is important to note that we also analyzed the stability of the DAR 1.5H:1V eastern side slope, which is currently underlain by about 7 feet of fill (see log for Boring B-2) and where the DAR will be raised by about 10 feet utilizing engineered fill. We utilized a phi angles of 28 to 30 degrees and respective cohesion of zero and 500 psf and obtained satisfactory FOS exceeding 1.5 and 1 for static and pseudo-static conditions, respectively, although we selected not to include the noted stability results plots.
CONCLUSIONS AND RECOMMENDATIONS

General
1. The Santa Clara Formation has significant compositional variation laterally and with depth. The formation’s comprising beds are reportedly lenticular in shape pinching and terminating laterally and their projection in the subsurface is unreliable. With this lithological variation, it is hard to predict what type of earth materials will be exposed along the final cut slope face and the potential for localized slope instabilities and/or significant erosion may prove to be high depending on what is exposed.

2. The Berrocal fault is a reverse fault that dips westward between 50 and 70 degrees separating the older Franciscan Complex greenstone bedrock to the west from the younger Santa Clara Formation sediments, which it has been thrust over, to the east. Norfleet (2008) indicated that it is unlikely that a specific fault plane exists and that the fault appears to be represented by a zone of shearing that measures between 50 and 100 feet in width instead. Furthermore, Sorg and McLaughlin (1975) mapped several bedrock fault traces immediately to the east of the NSP site and our Boring B-4 encountered a shear plane between 45 and 47 feet bgs.

3. The noted lithological variation of the formation underlying the site area coupled with the potential presence of fault-related shearing and polished slip surfaces could lead to exposing unfavorable conditions along the final cut slope face. Although Dibblee and Minch (2007) show the formation to have favorable bedding that trends northwest and dips northeastward into the hillside between 27 and 50 degrees in the vicinity of the site, concentrations of silty/clayey sands and poorly cemented gravelly zones could also be encountered along the cut slope face, which could result in high potential for erosion and surficial sloughing.

4. Our slope stability analysis did not account for localized granular sandy/gravelly zones, shear planes and seams, bedding attitudes, degree of weathering and spacing of discontinuities. Based on the above discussion, we recommend that our CEG is presented the opportunity to observe and map the cut slope during and immediately after the completion of the planned cuts so that adverse conditions are detected and mitigated in a timely manner.

5. If unfavorable conditions become apparent during grading, consideration should be given to overexcavating an approximately 20-foot wide band measured perpendicular to the slope face and then be placed back as engineered fill with 2H:1V gradient that is keyed, subdrained, compacted properly and reinforced with geogrid fabric, if deemed needed.

6. Based on our assessment and analysis, 2H:1V slope gradients are considered feasible and stable under both static and seismic loading.
7. An 8-foot wide drainage terrace/bench should be constructed at about mid-slope height to conform to the current California Building Code pertaining to manufactured slopes that are steeper than 3H:1V (33 percent slopes).

8. We estimated the NSP capacity to be about 4.4 acre-feet if the pond's side slopes are cut at an approximate gradient of 2H:1V and the DAR is raised by 10 feet at an approximate 1.5H:1V gradient.

9. Fill soils should be moisture conditioned, deposited in 8-inch thick loose lifts, and compacted to a minimum of 90 percent of the maximum dry density at near the optimum moisture content in accordance with ASTM method D1557.

10. The fill should be benched and keyed into the backcut slope as the fill placement progresses upslope. The fill slope face should be overbuilt and then trimmed back so that a uniform and compacted slope face is exposed. This recommendation is made because it is difficult to compact soil along the outer edge of the fill prism, which is needed to help prevent the occurrence of subsequent shallow slope failures and localized slumps.

11. Any fill placement and compaction should be performed under the direct observation of the project Geotechnical Engineer and/or his field representatives. Field observation and compaction testing should be performed periodically so that the process of fill placement, moisture conditioning, and compaction effort (if any) is consistent.

Plan Review
We recommend that BAGG Engineers is retained to review the final grading plans. This review will assess general suitability of earthwork and drainage design elements and to verify the appropriate implementation of such elements into the project plans and specifications.

Grading Observation
We recommend that our CEG is presented the opportunity to observe the planned grading to assess the potential presence of adverse geologic conditions that could impact the stability of the final slope faces to be cut. This is intended to verify that adverse geologic conditions are detected and mitigated during and not after its completion. Timely grading observations are important to verify that subsurface conditions encountered during construction are similar to those anticipated during the design phase. Unanticipated soil conditions may warrant revised recommendations. Therefore, BAGG cannot accept responsibility for the recommendations contained in this report if we are not retained to provide observation services during construction.

CLOSURE
This report has been prepared in accordance with generally accepted engineering geology and geotechnical engineering practices for the strict use of Stevens Creek Quarry in Cupertino, and other professionals associated with the specific project described in this report. The recommendations
presented in this report are based on our understanding of the proposed project as described herein and as shown on the provided site plans that show pre- and post-grading at the site of the New Settling Pond.

The conclusions and recommendations contained in this report are based on our review of available published geologic literature prepared by the USGS and CGS and site-specific studies prepared by other consultants, the observations of our CEG, subsurface exploration findings, limited laboratory testing, and stability analyses results. It is not uncommon for unanticipated conditions to be encountered during site grading and it is not possible for all such variations to be detected by our limited program for this type of project. The recommendations contained in this report are therefore contingent upon the review of the final grading and drainage plans by this office, and upon engineering geologic observation by our CEG of all pertinent aspects of site grading, including excavating and any slope rebuild.

Subsurface conditions and standards of practice change with time. Therefore, we should be consulted to update this report, if grading and construction does not commence within five years from the date this report provided that the site conditions, the building code and/or standard of practice in this area do not change significantly. Additionally, the recommendations of this report are only valid for the proposed project as described herein. If the proposed project is modified, our recommendations should be reviewed and approved or adjusted by this office in writing.

We trust this letter report provides you with the information required at this time. If you have any questions, please feel free to contact us.

Very truly yours,

BAGG Engineers

Sadek M. Derrega, PG, CEG #2175
Principal Engineering Geologist

Plate: 3

af  Artificial Fill (Historic) -- Loose to very well consolidated gravel, silt, sand, clay, rock fragments, organic matter, and man-made debris in various combinations. Thickness is variable and may exceed 30 meters in places. Some is compacted and quite firm, but fill made before 1965 is nearly everywhere not compacted and consists simply of dumped materials.

Qls  Landslide Deposits (Pleistocene and/or Holocene) -- Poorly sorted clay, silt, sand and gravel. Only a few very large landslides have been mapped. For a more complete map of landslide deposits, see Nilsen and others (1979).

Qsc  Santa Clara Formation (lower Pleistocene and upper Pliocene) -- Gray to red brown poorly indurated conglomerate, sandstone, and mudstone in irregular and lenticular beds. Conglomerate consists mainly of subangular to subrounded cobbles in a sandy matrix but locally includes pebbles and boulders. On Coal Mine Ridge, south of Portola Valley, conglomerate contains boulders of an older conglomerate as long as one meter. Gray to buff claystone and siltstone beds on Coal Mine Ridge, contain carbonized wood fragments as large as 60 cm in diameter. Included in Santa Clara Formation are similar coarse-grained clastic deposits near Burlingame. Sarna-Wojcicki (1976) found a tuff bed in Santa Clara Formation near Woodside, and correlated it with a similar tuff in the Merced Formation. Later work indicated that the tuff correlates with the 435 ka Rockland ash (Sarna-Wojcicki, oral comm., 1997). Thickness is variable but reaches a maximum of about 500 meters along Coal Mine Ridge.

fg  Greenstone of Franciscan Complex (Cretaceous and Jurassic) -- Dark green to red altered basaltic rocks, including flows, pillow lavas, breccias, tuff breccias, tuffs, and minor related intrusive rocks, in unknown proportions. Unit includes some Franciscan chert and limestone bodies that are too small to show on map. Greenstone crops out in lenticular bodies varying in thickness from a few meters to many hundreds of meters.

fsr  Sheared Rock (melange) of Franciscan Complex (Cretaceous and Jurassic) -- Predominantly graywacke, siltstone, and shale, substantial portions of which have been sheared, but includes hard blocks of all other Franciscan rock types. Total thickness of unit is unknown, but is probably at least several tens of meters.

### Coarse-Grained Soils

#### Major Divisions: Gravels
- **GW**: Well graded gravel, Well graded gravel with sand
- **GM**: Silty gravel, Silty gravel with sand
- **GC**: Clayey gravel, Clayey gravel with sand
- **SW**: Well graded sand, Well graded sand with gravel
- **SP**: Poorly graded sand, Poorly graded sand with gravel
- **SM**: Silty sand, Silty sand with gravel
- **SC**: Clayey sand, Clayey sand with gravel

#### Major Divisions: Sands
- **GRANULAR**: More than half of coarse fraction is smaller than No. 4 sieve size

### Fine-Grained Soils

#### Major Divisions: Silts and Clays
- **CL**: Lean clay, Sandy lean clay with gravel
- **ML**: Silt, Sandy silt with gravel
- **OL**: Organic clay, Sandy organic clay with gravel
- **CH**: Fat clay, Sandy fat clay with gravel
- **MH**: Elastic silt, Sandy elastic silt with gravel
- **OH**: Organic clay, Sandy organic clay with gravel
- **PT**: Peat, Highly organic silt

#### Major Divisions: Silts and Clays
- **SILTS**: Liquid limit more than 50
- **CLAYS**: Liquid limit less than 50

### Plasticity Chart

**FOR FINE-GRAINED SOILS AND FINE FRACTION OF COARSE-GRAINED SOILS**

**Note:** Classification is based on the portion of a sample that passes the 3-inch sieve.

**General Notes:** The tables list 30 out of a possible 110 Group Names, all of which are assigned to unique proportions of constituent soils. Flow charts in ASTM D 2487-06 aid assignment of the Group Names. Some general rules for fine-grained soils are: less than 15% sand or gravel is not mentioned; 15% to 25% sand or gravel is termed "with sand" or "with gravel", and 30% to 49% sand or gravel is termed "sandy" or "gravelly". Some general rules for coarse-grained soils are: uniformly-graded or gap-graded soils are "Poorly" graded (SP or GP); 15% or more sand or gravel is termed "with sand" or "with gravel", 15% to 25% clay and silt is termed clayey and silty and any cobbles or boulders are termed "with cobbles" or "with boulders".

**Reference:** ASTM D 2487-06, Standard Classification of Soils for Engineering Purposes (Unified Soil Classification System).
SOIL TYPES (Ref 1)

Boulders: particles of rock that will not pass a 12-inch screen.

Cobbles: particles of rock that will pass a 12-inch screen, but not a 3-inch sieve.

Gravel: particles of rock that will pass a 3-inch sieve, but not a #4 sieve.

Sand: particles of rock that will pass a #4 sieve, but not a #200 sieve.

Silt: soil that will pass a #200 sieve, that is non-plastic or very slightly plastic, and that exhibits little or no strength when dry.

Clay: soil that will pass a #200 sieve, that can be made to exhibit plasticity (putty-like properties) within a range of water contents, and that exhibits considerable strength when dry.

MOISTURE AND DENSITY

Moisture Condition: an observational term; dry, moist, wet, or saturated.

Moisture Content: the weight of water in a sample divided by the weight of dry soil in the soil sample, expressed as a percentage.

Dry Density: the pounds of dry soil in a cubic foot of soil.

DESCRIPTORS OF CONSISTENCY (Ref 3)

Liquid Limit: the water content at which a soil that will pass a #40 sieve is on the boundary between exhibiting liquid and plastic characteristics. The consistency feels like soft butter.

Plastic Limit: the water content at which a soil that will pass a #40 sieve is on the boundary between exhibiting plastic and semi-solid characteristics. The consistency feels like stiff putty.

Plasticity Index: the difference between the liquid limit and the plastic limit, i.e. the range in water contents over which the soil is in a plastic state.

MEASURES OF CONSISTENCY OF COHESIVE SOILS (CLAYS) (Ref's 2 & 3)

**WEATHERING DESCRIPTORS**

<table>
<thead>
<tr>
<th>Descriptor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fresh</td>
<td>No discoloration, not oxidized, no separation, hammer rings when crystalline rocks are struck.</td>
</tr>
<tr>
<td>Slight</td>
<td>Discoloration or oxidation is limited to surface of, or short distance from, fractures; some feldspar crystals are dull, no visible separation, hammer rings when crystalline rocks are struck, body of rock not weakened.</td>
</tr>
<tr>
<td>Moderate</td>
<td>Discoloration extends from fractures, usually throughout; Fe-Mg materials are &quot;rusty&quot;, feldspar crystals are &quot;cloudy&quot;, all fractures are discolored or oxidized, partial separation of boundaries visible, texture generally preserved, hammer does not ring when rock is struck, body of rock is slightly weakened.</td>
</tr>
<tr>
<td>Intense</td>
<td>Discoloration or oxidation throughout; all feldspars and Fe-Mg minerals are altered to clay to some extent; or chemical alteration produces in situ disaggregation, all fracture surfaces are discolored or oxidized, surfaces friable, partial separation, texture altered by chemical disintegration, dull sound when struck with hammer, rock is significantly weakened.</td>
</tr>
<tr>
<td>Decomposed</td>
<td>Discolored or oxidized throughout, but resistant mineral such as quartz may be unaltered, all feldspars and Fe-Mg minerals are completely altered to clay, complete separation of grain boundaries visible, resembles a soil, partial or complete remnant of rock structure may be preserved, can be granulated by hand, resistant minerals such as quartz may be present as &quot;stringers&quot; or &quot;dykes&quot;.</td>
</tr>
</tbody>
</table>

</thead>
<tbody>
<tr>
<td>Extremely Hard</td>
<td>Core, fragment, or exposure cannot be scratched with knife or sharp pick; can only be chipped with repeated heavy hammer blows.</td>
</tr>
<tr>
<td>Very Hard</td>
<td>Cannot be scratched with knife or sharp pick. Core or fragment breaks with repeated heavy hammer blows.</td>
</tr>
<tr>
<td>Hard</td>
<td>Can be scratched with knife or sharp pick with difficulty (heavy pressure). Heavy hammer blow required to break specimen.</td>
</tr>
<tr>
<td>Moderately Hard</td>
<td>Can be scratched with knife or sharp pick with light or moderate pressure. Core or fragment breaks with moderate hammer blow.</td>
</tr>
<tr>
<td>Moderately Soft</td>
<td>Can be grooved 1/16 inch (2mm) deep by knife or sharp pick with moderate or heavy pressure. Core fragment breaks with light hammer blow or heavy manual pressure.</td>
</tr>
<tr>
<td>Soft</td>
<td>Can be grooved or gouged easily by knife or sharp pick with light pressure, can be scratched with fingernail. Breaks with light to moderate manual pressure.</td>
</tr>
<tr>
<td>Very Soft</td>
<td>Can be readily indented, grooved, or gouged with fingernail, or carved with a knife. Breaks with light manual pressure.</td>
</tr>
</tbody>
</table>

*Note: Although "sharp pick" is included in those definitions, descriptions of ability to be scratched, grooved, or gouged by a knife is the preferred criteria.

**ROCK TERMINOLOGY**

---

GENERAL NOTES FOR BORING LOGS:

The boring logs are intended for use only in conjunction with the text, and for only the purposes the text outlines for our services. The Plate "Soil Terminology" defines common terms used on the boring logs.

The plate "Unified Soil Classification System," illustrates the method used to classify the soils. The soils were visually classified in the field; the classifications were modified by visual examination of samples in the laboratory, supported, where indicated on the logs, by tests of liquid limit, plasticity index, and/or gradation. In addition to the interpretations for sample classification, there are interpretations of where stratum changes occur between samples, where gradational changes substantively occur, and where minor changes within a stratum are significant enough to log.

There may be variations in subsurface conditions between borings. Soil characteristics change with variations in moisture content, with exchange of ions, with loosening and densifying, and for other reasons. Groundwater levels change with seasons, with pumping, from leaks, and for other reasons. Thus boring logs depict interpretations of subsurface conditions only at the locations indicated, and only on the date(s) noted.

SPECIAL FIELD NOTES FOR THIS REPORT:

1. The borings were drilled December 17 through December 20, 2018 with a truck mounted drilling rig using 8-inch diameter hollow stem augers. The borings were sealed with neat cement grout after the last soil sample was collected.

2. The boring locations were approximately located by pacing from known points on the site, as shown on Plate 2, Site Plan – Existing Topography and Plate 3, Site Plan – Proposed Topography.

3. The soils’ Group Names [e.g. SANDY LEAN CLAY] and Group Symbols [e.g. (CL)] were determined or estimated per ASTM D 2487-06, Standard Classification of Soils for Engineering Purposes (Unified Soil Classification System, see Plate 6). Other soil engineering terms used on the boring log are defined on Plate 6A, Soil Terminology and Plate 7, Rock Terminology.

4. The “Blow Count” Column on the boring logs indicates the number of blows required to drive the sampler below the bottom of the boring, with the blow counts given for each 6 inches of sampler penetration.

5. Perched free water was encountered in Boring B-3 at approximately 9 feet bgs and was measured at 8 feet bgs upon completion of boring.

6. The tabulated strength values on the boring logs are peak strength values.

BORING LOG NOTES
## Key to Symbols

### Strata Symbols
- **Aggregate Base**
- **Clayey sand**
- **Silty sand**
- **Silty sand with gravel**
- **Clayey sand with gravel**
- **Sandy lean clay**
- **Well graded sand with clay**
- **Sandy lean clay with gravel**
- **Silty & clayey sand**
- **Lean clay with sand**
- **Lean clay with sand and gravel**
- **Lean clay with silt**
- **Lean Clay**

### Miscellaneous Symbols
- **Boring continues**
- **Water first encountered during drilling**
- **Water level at completion of boring**
- **Drilling refusal**

### Soil Samplers
- **Modified California Sampler:** 24" long, 2.375" ID by 3" OD, split-barrel sampler driven w/ 140-pound hammer falling 30 inches (ASTM D3550)
- **Standard Penetration Test:** 24" long, 1.375" ID by 2" OD, split-spoon sampler driven w/ 140-pound hammer falling 30 inches (ASTM D1586-11)

### Line Types
- **Denotes a sudden, or well identified strata change**
- **Denotes a gradual, or poorly identified strata change**

Important Information about This Geotechnical-Engineering Report

Subsurface problems are a principal cause of construction delays, cost overruns, claims, and disputes.

While you cannot eliminate all such risks, you can manage them. The following information is provided to help.

The Geoprofessional Business Association (GBA) has prepared this advisory to help you – assumedly a client representative – interpret and apply this geotechnical-engineering report as effectively as possible. In that way, clients can benefit from a lowered exposure to the subsurface problems that, for decades, have been a principal cause of construction delays, cost overruns, claims, and disputes. If you have questions or want more information about any of the issues discussed below, contact your GBA-member geotechnical engineer. Active involvement in the Geoprofessional Business Association exposes geotechnical engineers to a wide array of risk-confrontation techniques that can be of genuine benefit for everyone involved with a construction project.

Geotechnical-Engineering Services Are Performed for Specific Purposes, Persons, and Projects
Geotechnical engineers structure their services to meet the specific needs of their clients. A geotechnical-engineering study conducted for a given civil engineer will not likely meet the needs of a civil-works constructor or even a different civil engineer. Because each geotechnical-engineering study is unique, each geotechnical-engineering report is unique, prepared solely for the client. Those who rely on a geotechnical-engineering report prepared for a different client can be seriously misled. No one except authorized client representatives should rely on this geotechnical-engineering report without first conferring with the geotechnical engineer who prepared it. And no one – not even you – should apply this report for any purpose or project except the one originally contemplated.

Read this Report in Full
Costly problems have occurred because those relying on a geotechnical-engineering report did not read it in its entirety. Do not rely on an executive summary. Do not read selected elements only. Read this report in full.

You Need to Inform Your Geotechnical Engineer about Change
Your geotechnical engineer considered unique, project-specific factors when designing the study behind this report and developing the confirmation-dependent recommendations the report conveys. A few typical factors include:
- the client's goals, objectives, budget, schedule, and risk-management preferences;
- the general nature of the structure involved, its size, configuration, and performance criteria;
- the structure's location and orientation on the site; and
- other planned or existing site improvements, such as retaining walls, access roads, parking lots, and underground utilities.

Typical changes that could erode the reliability of this report include those that affect:
- the site's size or shape;
- the function of the proposed structure, as when it's changed from a parking garage to an office building, or from a light-industrial plant to a refrigerated warehouse;
- the elevation, configuration, location, orientation, or weight of the proposed structure;
- the composition of the design team; or
- project ownership.

As a general rule, always inform your geotechnical engineer of project changes – even minor ones – and request an assessment of their impact. The geotechnical engineer who prepared this report cannot accept responsibility or liability for problems that arise because the geotechnical engineer was not informed about developments the engineer otherwise would have considered.

This Report May Not Be Reliable
Do not rely on this report if your geotechnical engineer prepared it:
- for a different client;
- for a different project;
- for a different site (that may or may not include all or a portion of the original site); or
- before important events occurred at the site or adjacent to it; e.g., man-made events like construction or environmental remediation, or natural events like floods, droughts, earthquakes, or groundwater fluctuations.

Note, too, that it could be unwise to rely on a geotechnical-engineering report whose reliability may have been affected by the passage of time, because factors like changed subsurface conditions, new or modified codes, standards, or regulations; or new techniques or tools. If your geotechnical engineer has not indicated an "apply-by" date on the report, ask what it should be, and, in general, if you are the least bit uncertain about the continued reliability of this report, contact your geotechnical engineer before applying it. A minor amount of additional testing or analysis – if any is required at all – could prevent major problems.

Most of the "Findings" Related in This Report Are Professional Opinions
Before construction begins, geotechnical engineers explore a site's subsurface through various sampling and testing procedures. Geotechnical engineers can observe actual subsurface conditions only at those specific locations where sampling and testing were performed. The data derived from that sampling and testing were reviewed by your geotechnical engineer, who then applied professional judgment to form opinions about subsurface conditions throughout the site. Actual sitewide-subsurface conditions may differ – maybe significantly – from those indicated in this report. Confront that risk by retaining your geotechnical engineer to serve on the design team from project start to project finish, so the individual can provide informed guidance quickly, whenever needed.
This Report's Recommendations Are Confirmation-Dependent

The recommendations included in this report – including any options or alternatives – are confirmation-dependent. In other words, they are not final, because the geotechnical engineer who developed them relied heavily on judgment and opinion to do so. Your geotechnical engineer can finalize the recommendations only after observing actual subsurface conditions revealed during construction. If through observation your geotechnical engineer confirms that the conditions assumed to exist actually do exist, the recommendations can be relied upon, assuming no other changes have occurred. The geotechnical engineer who prepared this report cannot assume responsibility or liability for confirmation-dependent recommendations if you fail to retain that engineer to perform construction observation.

This Report Could Be Misinterpreted

Other design professionals' misinterpretation of geotechnical-engineering reports has resulted in costly problems. Confront that risk by having your geotechnical engineer serve as a full-time member of the design team, to:

- confer with other design-team members,
- help develop specifications,
- review pertinent elements of other design professionals' plans and specifications, and
- be on hand quickly whenever geotechnical-engineering guidance is needed.

You should also confront the risk of constructors misinterpreting this report. Do so by retaining your geotechnical engineer to participate in prebid and preconstruction conferences and to perform construction observation.

Give Constructors a Complete Report and Guidance

Some owners and design professionals mistakenly believe they can shift unanticipated-subsurface-conditions liability to constructors by limiting the information they provide for bid preparation. To help prevent the costly, contentious problems this practice has caused, include the complete geotechnical-engineering report, along with any attachments or appendices, with your contract documents, but be certain to note conspicuously that you’ve included the material for informational purposes only. To avoid misunderstanding, you may also want to note that “informational purposes” means constructors have no right to rely on the interpretations, opinions, conclusions, or recommendations in the report, but they may rely on the factual data relative to the specific times, locations, and depths/elevations referenced. Be certain that constructors know they may learn about specific project requirements, including options selected from the report, only from the design drawings and specifications. Remind constructors that they may perform their own studies if they want to, and be sure to allow enough time to permit them to do so. Only then might you be in a position to give constructors the information available to you, while requiring them to at least share some of the financial responsibilities stemming from unanticipated conditions. Conducting prebid and preconstruction conferences can also be valuable in this respect.

Read Responsibility Provisions Closely

Some client representatives, design professionals, and constructors do not realize that geotechnical engineering is far less exact than other engineering disciplines. That lack of understanding has nurtured unrealistic expectations that have resulted in disappointments, delays, cost overruns, claims, and disputes. To confront that risk, geotechnical engineers commonly include explanatory provisions in their reports. Sometimes labeled “limitations,” many of these provisions indicate where geotechnical engineers’ responsibilities begin and end, to help others recognize their own responsibilities and risks. Read these provisions closely. Ask questions. Your geotechnical engineer should respond fully and frankly.

Geoenvironmental Concerns Are Not Covered

The personnel, equipment, and techniques used to perform an environmental study – e.g., a “phase-one” or “phase-two” environmental site assessment – differ significantly from those used to perform a geotechnical-engineering study. For that reason, a geotechnical-engineering report does not usually relate any environmental findings, conclusions, or recommendations; e.g., about the likelihood of encountering underground storage tanks or regulated contaminants. Unanticipated subsurface environmental problems have led to project failures. If you have not yet obtained your own environmental information, ask your geotechnical consultant for risk-management guidance. As a general rule, do not rely on an environmental report prepared for a different client, site, or project, or that is more than six months old.

Obtain Professional Assistance to Deal with Moisture Infiltration and Mold

While your geotechnical engineer may have addressed groundwater, water infiltration, or similar issues in this report, none of the engineer’s services were designed, conducted, or intended to prevent uncontrolled migration of moisture – including water vapor – from the soil through building slabs and walls and into the building interior, where it can cause mold growth and material-performance deficiencies. Accordingly, proper implementation of the geotechnical engineer’s recommendations will not of itself be sufficient to prevent moisture infiltration. Confront the risk of moisture infiltration by including building-envelope or mold specialists on the design team. Geotechnical engineers are not building-envelope or mold specialists.
